

Atheniks

Industry Solutions — Technical Documentation

For: Nikolai Sivtsev, Co-Founder & CTO

From: Maxim Neimeier, Co-Founder & CEO

Date: March 2026

Covered Industries:

1. Construction & Real Estate Development
2. Facility Management
3. Utilities & Renewable Energy
4. Logistics & Freight

Purpose of This Document

This document gives you — as co-founder and CTO — everything you need to understand why we are building industry-specific solutions, what each industry needs, how Atheniks solves those needs technically, and what we need to build.

Each industry section covers:

- Why this industry is a good target market
- What pain points finance and controlling teams face every day
- What existing tools they use and why those tools fail
- What Atheniks needs to deliver — specific data models, calculations, and features
- What the competitive gap looks like
- What success looks like for a pilot customer

Read this before our next product planning session. The goal is to align on what we build first, why, and in what order.

Industry 1: Construction & Real Estate Development

General contractors, subcontractors, and property developers with 20–200 employees

Why This Industry

Construction is our highest-priority target. The combination of extreme financial complexity, poor tooling for the mid-market segment, and clear pain that repeats with every single project makes this the best entry market for Atheniks.

Market size (DACH)	Approx. €420B annual construction volume, around 40,000 mid-market firms with 20–500 employees
Financial complexity	Highest of all four industries — project-based costing, multi-year cash flows, legal provisions required
Current tooling	Excel and accounting software only. No mid-market tool combines project finance, accounting, and provisions
Sales cycle	3–6 weeks — the CFO or financial controller is the decision maker, pain is immediate and recurring
Priority	P1 — build and sell first

The Core Problem

Construction finance is not like standard business finance. Every project is effectively a small company with its own revenue, costs, timeline, and risk. Finance teams must manage this across 5–50 simultaneous projects with a small team, using tools that were never designed for this purpose.

Problem 1: Contract Completion Provisions

Under German accounting law, construction companies are legally required to book provisions for anticipated losses or cost overruns on any uncompleted contract where total expected costs exceed the contract value. This is a legal requirement, not optional.

How it works today:

- The controller manually reviews each active project every month
- They calculate estimated total cost versus contract revenue for each project
- If expected costs exceed revenue at any stage, a provision must be booked in the accounting system
- With 20 or more active projects, this takes 2 to 3 days of manual work every month
- The provision amounts must match accounting entries exactly — any mismatch creates audit problems

What Atheniks must do

Automatically calculate the required provision per project based on current cost actuals from the accounting system, remaining budget from the project plan, contract value, and percentage of completion. Pre-fill the accounting journal entry and require only controller approval. The goal is to eliminate the manual 2-day monthly process entirely.

Problem 2: Equipment Depreciation

Construction companies own expensive equipment — excavators, cranes, concrete mixers. All of this depreciates over time. Tracking depreciation is standard accounting, but in construction it is complicated because:

- Equipment is often partially allocated to specific projects, which affects project cost calculations
- Equipment financing mixes leasing contracts, bank loans, and outright ownership
- Depreciation entries must be posted to the accounting system monthly with correct asset account codes
- Controllers maintain asset registers manually in spreadsheets or separate tools

What Atheniks must do

Maintain a structured asset register with acquisition cost, useful life, depreciation method (straight-line or declining balance), and current book value. Automatically calculate monthly depreciation per asset, allocate costs to projects where relevant, and generate the accounting journal entries automatically.

Problem 3: Project Cost Tracking

The central question in construction finance is: is this project on budget? Answering it requires combining four different data sources:

- Actual costs to date — invoices paid and wages posted in the accounting system
- Committed costs — signed subcontractor contracts not yet invoiced
- Forecast costs to complete — estimates from site management on remaining work
- Remaining contract value — what is still billable to the client

None of this lives in one system today. Controllers reconcile it all manually in spreadsheets.

What Atheniks must do

Create a project financial model where actual costs flow from the accounting system via API, committed costs are entered manually or imported from purchase orders, and forecast-to-complete is entered by project managers. Atheniks calculates the full project profit and loss in real time and automatically flags any project that is over budget.

Technical Requirements

Data Model

Core entities needed:

- Project — ID, name, contract value, start and end date, client, contract type
- Project Budget — budget lines per cost category: labor, materials, subcontractors, equipment, overhead
- Cost Entry — actual cost, source (accounting sync or manual entry), project allocation, date
- Committed Cost — subcontractor contract value, scope, and expected invoice dates
- Forecast to Complete — controller estimate for remaining cost in each category
- Provision — calculated provision amount, booking date, and accounting code
- Asset — acquisition cost, useful life, depreciation method, monthly depreciation amount, project allocations

Key Calculations

Calculation	Formula	Output
Project margin	Contract value minus (actuals + committed + forecast)	Amount in euros and as a percentage
Completion percentage	Actuals divided by total budget	Percentage used for revenue recognition
Required provision	Maximum of zero and (total expected cost minus contract value)	Provision amount to book
Monthly depreciation	Acquisition cost divided by useful life in months	Per asset, per month
Cash forecast	Billing milestones minus committed outflows	Monthly cash position per project

Accounting Integration

This is the critical integration for the construction module. The accounting system holds the authoritative actual cost data and our figures must match it exactly.

- Read: import actual cost entries via accounting API — invoices paid, wages posted, overhead allocated
- Write: export journal entries for provisions and depreciation in standard accounting format
- Account mapping: user-configurable mapping of Atheniks cost categories to accounting chart of accounts
- Fiscal periods: respect the company's fiscal year setup, which may not align with the calendar year

Competitive Gap

Tool	What it does	What is missing
------	--------------	-----------------

Accounting software only	Records transactions and actuals	No project view, no forecasting, no provisions calculation
Enterprise ERP (SAP, Dynamics)	ERP with project modules	Costs over €50,000 to set up, requires IT staff, not accessible for small and mid-size companies
Construction project tools	Project scheduling and task management	No accounting integration, no provisions, not finance-ready
Spreadsheets	Everything done manually	No automation, no audit trail, breaks at scale
Atheniks Construction module	Project finance plus accounting integration	This is the gap we are filling

What a Successful Pilot Looks Like

Target customer: a construction company with 30 to 80 employees, 10 to 30 active projects, currently using spreadsheets and accounting software only.

Week 1 to 2: Connect the accounting system, import existing projects, set up the asset register.

Week 3 to 4: Controller approves auto-calculated provisions for the current month.

Month 2: First month where the provisions workflow requires zero manual spreadsheet work.

Month 3: Controller saves 2 or more days per month, project margin visibility is real-time.

Success metric

The controller can see whether every project is on budget at any time, and the monthly provisions process no longer requires a spreadsheet.

Industry 2: Facility Management

Commercial and residential facility management companies with 20–200 employees

Why This Industry

Facility management is our second priority because the product overlap with construction is very high — approximately 70 percent of what we build for construction works immediately for FM. The pain is different but equally recurring and financially significant.

Market size (DACH)	Approx. €80B annual FM market, around 15,000 companies with 10–200 employees
Financial complexity	High — contract-based recurring revenue, maintenance cycles, headcount-heavy cost structure
Current tooling	Operational FM software plus separate accounting. No unified finance layer exists for this segment
Sales cycle	4–8 weeks — pain less acute than construction but very clear and recurring
Priority	P2 — build after construction with minimal additional development required

The Core Problem

Facility management finance looks simple on the surface — you have service contracts, you deliver services, you invoice. In practice it is much more complex because:

- Contracts often have variable scope with a base service level plus ad-hoc extras and emergency call-outs
- Planned maintenance cycles create uneven cost distribution across the year
- Labor is 60 to 70 percent of total costs and must be allocated to individual contracts to understand profitability
- Equipment maintenance creates questions about capital versus operating expense classification
- Multi-building or multi-site contracts require profitability tracking per individual location

Problem 1: Maintenance Reserve Tracking

For FM companies managing residential properties, there is a legal requirement to maintain reserves for future major maintenance expenditure. This is separate from day-to-day operating costs and must be tracked per property.

Current situation:

- Controllers manually calculate the required reserve per property based on size and building age
- Actual contributions versus required reserves are tracked in separate spreadsheets

- When a major maintenance event occurs, the drawdown from reserves must be booked correctly in accounting
- Annual property owner reports require a full reconciliation of reserve movements

What Atheniks must do

Track maintenance reserves per property: annual contribution required, actual contributions collected, current reserve balance, and planned drawdowns for scheduled maintenance. Generate the annual reserve reconciliation report automatically so controllers do not have to build it in a spreadsheet.

Problem 2: Contract Profitability Tracking

An FM company with 50 service contracts needs to know which contracts make money and which do not. This requires allocating all costs to the contract level:

- Direct labor: hours worked per contract, either imported from a time-tracking tool or entered manually
- Materials consumed on each contract during the period
- Subcontractor costs assigned to each contract
- Equipment depreciation for machinery used on specific contracts
- Overhead allocation: a fair share of office costs, management time, and insurance

Without this allocation, the finance team only sees total company revenue and total costs. Unprofitable contracts are completely invisible.

What Atheniks must do

Build a contract cost allocation model where labor hours, material costs, and overhead rates are all assigned to each service contract. Calculate gross margin per contract and automatically flag any contract running below the target margin threshold.

Problem 3: Planned Maintenance Forecasting

Scheduled maintenance creates predictable but uneven cost spikes throughout the year. A building that needs HVAC service in March, fire safety inspection in June, and elevator servicing in September creates very lumpy cash outflows. Finance teams need to:

- Know in advance when significant maintenance costs will occur
- Budget correctly for the full year during the annual planning cycle
- Track whether scheduled maintenance was completed on time and within budget

What Atheniks must do

Maintain a maintenance schedule per property or contract. For each planned maintenance event: expected date, budget, and responsible subcontractor or supplier. Feed this schedule into the cash flow forecast automatically so finance can see upcoming cost spikes before they occur.

Technical Requirements

Additional Data Model (on top of construction base)

- Service Contract — client, locations covered, scope, contract value, billing frequency, start and end date
- Maintenance Event — type, scheduled date, actual completion date, budget, actual cost, status
- Maintenance Reserve — property ID, annual contribution required, current balance, drawdown history
- Labor Allocation — employee or team, hours worked, contract assigned, week
- Contract Margin — revenue, direct costs, overhead allocation, net margin per contract

Key Calculations

Calculation	Formula	Output
Contract margin	Contract revenue minus (direct costs plus overhead allocation)	Amount in euros and as a percentage per contract
Overhead rate	Total overhead divided by total direct labor hours	Cost per hour for allocation to contracts
Reserve adequacy	Current balance divided by next 12 months of planned maintenance	Coverage ratio
Maintenance variance	Actual maintenance cost minus budgeted cost	Per event and per property
Annual reserve reconciliation	Opening balance plus contributions minus drawdowns	Closing reserve balance per property

Competitive Gap

Tool	What it does	What is missing
Enterprise CAFM software	Operational workflows, asset tracking, work orders	Very expensive, no finance layer, no accounting integration
Enterprise asset management	Large-scale asset lifecycle management	Enterprise-only pricing, no FM finance model
Accounting software only	Records all financial transactions	No contract view, no maintenance planning, no profitability by contract
Spreadsheets	Manual tracking of everything	No automation, inconsistent results, breaks with scale
Atheniks FM module	Finance layer on top of FM operations	The gap that does not exist today in any mid-market product

Why This Requires Minimal Extra Development

The construction module already builds the following components, which work directly for FM:

- Project and contract cost tracking — same underlying data model, just different terminology
- Accounting integration — same connection, same accounting rules apply
- Asset register with depreciation — same model, FM companies simply have more and different asset types
- Monthly provisions calculation — same engine, different provision type and calculation inputs

What is genuinely new for FM and not reused from construction:

- Maintenance reserve calculation and balance tracking
- Annual property owner report template
- Labor allocation model connecting hours worked to specific contracts
- Maintenance cycle calendar integrated into the cash flow forecast

Development estimate

If the construction module represents 100 percent of the initial build effort, the FM module adds approximately 20 to 25 percent of additional work on top. Most of it is reporting and user interface work, not new data model logic or calculations.

Industry 3: Utilities & Renewable Energy

Independent renewable energy operators — solar, wind, biogas — running 3 to 50 plants

Why This Industry

This is not traditional utility companies. Our target is the fast-growing segment of independent renewable energy operators — companies that own and operate between 3 and 50 solar parks, wind farms, or biogas plants. This segment is large, growing rapidly, completely underserved by software, and has very specific financial calculations that no mid-market tool handles today.

Market size (DACH)	Approx. 4,000 independent renewable operators, growing 20 to 30 percent annually with the energy transition
Financial complexity	High — government feed-in tariffs, plant-level profit and loss, 20-year asset lifecycles, project finance loan covenants
Current tooling	Spreadsheets for plant-level financials plus separate accounting. No integrated tool for operators of 3 to 50 plants
Sales cycle	6–12 weeks — decisions often involve both technical and finance stakeholders
Priority	P3 — requires one design partner to validate before full build begins

The Core Problem

Running 10 solar parks is not just bigger than running one — it is qualitatively more complex. Finance teams need to track performance, forecast revenue, manage regulatory compliance, and report to lenders, all at the individual plant level, in aggregate across the portfolio, and over very long time horizons of 20 years or more.

Problem 1: Feed-in Tariff Revenue Forecasting

In Germany and across Europe, renewable energy operators receive guaranteed feed-in tariffs for electricity generated, locked in for 20 years from the date of installation. This is the primary revenue stream for most solar and wind operators.

The complexity:

- Each plant has a different tariff rate locked in at the time of installation, which varies by year and technology type
- Monthly revenue equals kilowatt-hours produced multiplied by the tariff rate, but production varies with weather
- After the fixed tariff period ends, revenue switches to variable spot market pricing, which is a fundamentally different model
- Some operators participate in direct marketing programs that add a market premium on top of the base tariff

- Monthly settlement statements from the grid operator must be reconciled against the forecast

What Atheniks must do

Maintain a tariff register per plant: installation date, tariff rate, tariff expiry date, and current revenue model. Forecast monthly revenue based on historical production data and expected output. Automatically reconcile forecast against actual settlement statements received from the grid operator.

Problem 2: Plant-Level Profit and Loss

An operator with 15 solar parks needs to know whether each individual park is profitable. This requires allocating all costs down to the plant level:

- Operations and maintenance costs: service contracts for inverter maintenance, panel cleaning, and monitoring
- Land lease payments: fixed annual payments to the landowner, allocated monthly
- Insurance: split across plants by installed capacity or asset value
- Financing costs: each plant typically has its own project-specific bank loan with its own amortization schedule
- Depreciation: solar panels over 20 years, inverters over 10 to 12 years, civil infrastructure over 40 years

Operators cannot see plant-level profitability today. They only see total revenue and total costs in their accounting system.

What Atheniks must do

Build a plant financial model where every cost line is tagged to a specific plant. Calculate plant-level EBITDA, EBIT, and net profit on a monthly basis. Aggregate results to the portfolio level with the ability to drill down to any individual plant. This is the core value delivery of the energy module.

Problem 3: Lender Reporting and Financial Covenants

Renewable energy projects are typically financed with project-specific bank loans. These loans contain financial covenants that the operator must report on quarterly or annually. Common covenants include:

- Debt Service Coverage Ratio: cash available for debt service divided by total debt service payments
- Loan to Value ratio: outstanding loan balance divided by the plant's current market value
- Minimum cash balance: the operator's total cash cannot fall below a defined floor

Reporting these metrics manually to 3 to 5 different lenders, each with a different loan on a different plant, consumes significant finance team time every quarter.

What Atheniks must do

Track loan parameters per plant: outstanding balance, interest rate, amortization schedule, and covenant thresholds. Calculate the Debt Service Coverage Ratio and other covenant metrics every month. Generate lender reports in a standard format. Alert the finance team when any covenant is at risk of being breached.

Technical Requirements

Data Model Unique to Energy

- Plant — ID, name, location, technology type, installed capacity in kilowatts, installation date
- Tariff Contract — tariff rate, tariff type, contract expiry date, grid operator name
- Production Data — monthly kilowatt-hours per plant, imported from monitoring system or entered manually
- Land Lease — annual payment amount, landowner details, contract term, plant assignment
- Project Loan — lender, original amount, outstanding balance, interest rate, maturity date, covenant thresholds
- Maintenance Contract — operations and maintenance provider, annual fee, scope, plant coverage
- Plant Asset — component type, acquisition cost, useful life, depreciation schedule

Key Calculations

Calculation	Formula	Output
Monthly tariff revenue	kWh produced multiplied by tariff rate	Euros per plant per month
Plant EBITDA	Revenue minus operations and maintenance, land lease, and insurance	Euros per plant per month
Debt Service Coverage Ratio	EBITDA divided by annual debt service	Ratio per loan per year
Remaining tariff value	Monthly revenue multiplied by remaining tariff months	Asset value for refinancing purposes
Portfolio yield	Total net income divided by total invested capital	Return on investment across all plants

Integrations Needed

- Plant monitoring platforms: import kilowatt-hour production data via API or CSV file
- Grid operator settlement statements: PDF import or manual entry for monthly revenue reconciliation
- Accounting software: same integration as construction — actual costs in, journal entries out

- Banking: account balance import for liquidity tracking (optional in the first version)

Competitive Gap

Tool	What it does	What is missing
Enterprise utility management software	Full utility operations management	Enterprise pricing well above €100,000, not accessible to independent operators
Solar yield simulation tools	Engineering simulation for expected production	Engineering-only tools with no finance or accounting capability
Plant monitoring platforms	Real-time production tracking and alerts	No finance layer of any kind
Spreadsheets	Manual plant-level profit and loss	Not scalable beyond 3 to 5 plants, completely manual, error-prone
Atheniks Energy module	Plant finance, feed-in tariff tracking, lender reporting	Clear gap with no competitor serving the mid-market segment

Why We Need a Design Partner Before Building

Unlike construction and FM, energy has more regulatory detail — feed-in tariff structures, grid operator settlement formats — that we need to validate with an actual operator before committing to a specific build. We do not want to build the wrong version of the revenue calculation model.

Design partner criteria:

- Operates between 5 and 20 solar parks or wind farms
- Currently uses spreadsheets for plant-level profit and loss
- Has at least one project finance loan with covenant reporting obligations
- Is willing to share real operational data so we can validate our financial model

Next step

Maxim has a contact at a solar park operator in Bavaria. An interview is scheduled. The outcome determines whether we build the energy module as our third release or defer it.

Industry 4: Logistics & Freight

Freight forwarding and transport companies operating 10 to 200 vehicles

Why This Industry

Logistics is our fourth priority. The asset-heavy nature of transport operations creates recurring finance problems that are structurally similar to construction equipment management — but with additional complexity from vehicle fleet financing, lease accounting standards, and the need for per-vehicle profitability tracking.

Market size (DACH)	Approx. €280B logistics sector, around 25,000 mid-size companies with 10 to 200 vehicles
Financial complexity	High — fleet financing via leasing or loans, lease accounting under IFRS 16, per-vehicle cost allocation, fuel and toll cost tracking
Current tooling	Fleet management and telematics tools plus accounting software. No financial integration exists between them
Sales cycle	4–8 weeks — the CFO or owner-manager is the decision maker
Priority	P4 — build after energy, reuses significant work from the construction and FM modules

The Core Problem

A logistics company with 50 trucks is effectively running 50 individual cost centers simultaneously. Each vehicle has its own financing arrangement, maintenance schedule, assigned driver, and revenue contribution. Finance teams track almost none of this at the vehicle level — they see total company revenue and total costs, not the economics of each individual asset.

Problem 1: Lease Accounting Under IFRS 16

Most logistics companies finance their fleet through leasing rather than outright purchase. Since 2019, the international accounting standard IFRS 16 requires that operating leases be recognized on the balance sheet — a significant accounting change that many mid-market companies still handle incorrectly or inconsistently.

Under IFRS 16, for each lease contract:

- A Right-of-Use Asset must be recorded on the balance sheet at the start of the lease
- A corresponding Lease Liability must be recognized at the same time
- Each month: an interest expense is recognized, the liability is reduced by the principal portion of the payment, and the Right-of-Use Asset is depreciated
- This treatment affects EBITDA, EBIT, and Net Income differently than the old operating lease approach

Current situation in logistics companies:

- Many still book lease payments as a simple monthly operating expense, which is incorrect under IFRS 16
- Controllers who do apply IFRS 16 do the calculations manually in spreadsheets with complex amortization tables
- When a lease is modified or renewed, the entire calculation must be rebuilt from scratch

What Atheniks must do

For each lease contract, the user enters: start date, end date, monthly payment amount, and discount rate. Atheniks then calculates the initial Right-of-Use Asset value and Lease Liability, generates the full monthly amortization schedule for the entire lease term, and produces the correct accounting journal entries for each month automatically. Lease modifications are handled by recalculating the remaining liability.

Problem 2: Per-Vehicle Profit and Loss

To understand whether the fleet is actually profitable, finance needs to know the economics of each individual vehicle:

- Revenue: which jobs and routes were driven by this vehicle, imported from the transport management system
- Fuel costs: amount consumed and cost, imported from telematics or fuel card data
- Driver wages: allocated by hours driven in this vehicle
- Road tolls: monthly toll charges per vehicle, imported from the toll billing system
- Financing cost: the monthly lease payment or loan installment for this specific vehicle
- Maintenance: actual repair and servicing costs, including mandatory inspection fees
- Depreciation: if the vehicle is owned outright, the monthly depreciation charge

This calculation does not exist in any mid-market tool today. Fleet management tools track operational data. Accounting tools record costs. Nobody connects the two to produce per-vehicle economics.

What Atheniks must do

Build a vehicle financial model where each truck is treated as a small profit center. Revenue is allocated from the transport management system or entered manually. All cost categories are tagged per vehicle. Atheniks calculates the contribution margin per vehicle and identifies which assets are underperforming relative to their cost.

Problem 3: Maintenance and Inspection Planning

Like facility management, logistics has recurring mandatory maintenance events that create predictable but unplanned cash outflows:

- Mandatory vehicle inspection: required every 12 to 24 months, fixed cost, non-negotiable
- Planned service intervals: based on kilometers driven, fully predictable in advance

- Tire replacement: based on wear pattern, semi-predictable
- Emergency repairs: unpredictable individually, but a fleet-level budget can be set based on age and utilization

Finance teams need to budget for these costs and forecast when they will hit cash flow during the year.

What Atheniks must do

Maintain a maintenance calendar per vehicle. For each vehicle: the date of the next mandatory inspection, the next service interval based on current kilometer tracking, and the estimated cost. Feed this into the cash flow forecast. Alert the finance team when an inspection date is approaching and no budget has been set aside.

Technical Requirements

Data Model Unique to Logistics

- Vehicle — ID, license plate, type, make and model, year of manufacture, current odometer reading, ownership type
- Lease Contract — vehicle, start and end date, monthly payment, residual value, discount rate, lender
- IFRS 16 Schedule — Right-of-Use Asset value, Lease Liability, monthly interest, monthly depreciation — all auto-calculated
- Vehicle Job — vehicle, date, route, revenue from transport system, driver, distance, fuel consumption
- Fuel Record — vehicle, date, volume, price per unit, total cost
- Toll Record — vehicle, month, total toll charges imported from billing system
- Maintenance Event — vehicle, type, date, actual cost, service provider

Key Calculations

Calculation	Formula	Output
Initial Right-of-Use Asset	Present value of future lease payments at the discount rate	Euros at lease start date
Monthly lease interest	Opening liability multiplied by the monthly discount rate	Euros recognized as interest expense
Vehicle contribution margin	Revenue minus (fuel + driver wages + tolls + maintenance)	Euros and percentage per vehicle
Cost per kilometer	Total vehicle costs divided by kilometers driven	Euros per kilometer for benchmarking
Fleet EBITDA	Total revenue minus total direct costs before financing and depreciation	Portfolio-level view

Integrations Needed

- Transport Management System: job and route data for revenue allocation — supports standard CSV export from major systems
- Road toll billing: monthly toll charges imported from the national toll billing system in standard CSV format
- Telematics: fuel consumption and odometer data from tracking platforms or manual entry
- Accounting software: same integration as all other modules — actual costs in, journal entries out

Competitive Gap

Tool	What it does	What is missing
Fleet telematics platforms	GPS tracking, fuel data, driver behavior monitoring	No finance layer of any kind
Fleet management software	Maintenance scheduling, document management, basic reporting	No profit and loss, no lease accounting, no accounting integration
Enterprise transport management	Full enterprise-grade transport operations	Costs over €150,000, completely out of range for mid-market companies
Accounting software only	Records all financial transactions	No fleet view, no per-vehicle profit and loss, no lease accounting support
Atheniks Logistics module	Per-vehicle profit and loss plus lease accounting plus accounting integration	Does not exist for the mid-market segment

Work Reused from Earlier Modules

Because we build construction and FM first, the logistics module inherits the following components at no additional development cost:

- Asset register with depreciation — vehicles are assets, same underlying data model applies
- Accounting integration — same connection to the same accounting system
- Maintenance cycle planning — same data model as FM, adapted for vehicles instead of buildings
- Monthly provisions and liability tracking — engine can be adapted for lease liability management

What is genuinely new and unique to logistics:

- IFRS 16 calculation engine — the most complex new calculation across all four industries
- Vehicle job and route revenue allocation model
- Telematics and transport management system integrations

- Per-kilometer cost calculation and fleet benchmarking tool

Build Sequence and Shared Architecture

Why This Order

The four industries are not independent builds. They share a core technical architecture, and we can reuse substantial amounts of code across each industry layer. The sequence is designed to maximize reuse and minimize risk.

Phase	Industry	What is new compared to the previous phase
Phase 1	Construction	Everything — base platform, accounting integration, project profit and loss, provisions engine
Phase 2	Facility Management	Approximately 20 percent new — maintenance reserves, property owner report, labor allocation model
Phase 3	Utilities and Energy	Approximately 35 percent new — feed-in tariff model, plant profit and loss, lender reporting, production data import
Phase 4	Logistics	Approximately 30 percent new — IFRS 16 calculation engine, vehicle profit and loss, telematics integration

Shared Core Components

These components are built once and work across all four industries with minimal customization:

- Accounting integration layer — read actual costs, write journal entries, configurable account mapping
- Asset register with depreciation calculation — used in all four industries for different asset types
- Monthly provisions calculation engine — parameterizable by provision type and calculation inputs
- Cash flow forecast model — aggregates inputs from all cost and revenue streams
- Report generation — profit and loss, balance sheet impact, cash forecast, custom exports
- User management and access control — controller versus manager versus read-only roles

Ideal First Customer Profile

For each industry, the first customer we approach has the following characteristics:

Company size	30 to 80 employees for construction, 20 to 60 for FM, flexible for energy and logistics
Current tools	Spreadsheets and accounting software only — no modern financial planning tool in place
Finance team	1 to 3 controllers, at least one person who feels the daily pain directly
Budget	Willing to pay €500 to €1,500 per month for a tool that saves 2 or more days of manual work per month
Location	DACH region — Germany preferred for accounting integration validation
Stage	Company has been operating for 2 or more years and has real historical data to import

Open Questions for Next Product Session

- Accounting API access: which API endpoint do we use for the accounting integration — the modern API or the older document export service? We need to test both before deciding.
- Lease accounting standards: German mid-market companies sometimes use German commercial accounting rules rather than IFRS. Do we build both lease accounting models from the start or focus on IFRS 16 only for the first version?
- Multi-entity accounting: some FM and logistics companies have separate accounting mandants for different legal entities. How do we handle this in the data model?
- Export requirements: do customers need to export data for their external accountant or tax advisor? What file format do they expect?
- Mobile access: do controllers need a mobile view for on-site use, or is desktop-only acceptable for the first version?

Summary

Construction is our beachhead market. Facility Management is nearly free once Construction is built. Energy and Logistics require more genuinely new development but the market gap is equally clear. Build in this order: Construction, then Facility Management, then Energy, then Logistics. The shared architecture pays off significantly from Phase 2 onward.
